Class Notes
Separable Equations (Section 2.2)

What if we can isolate each variable and its differential on one side of the equation?
Could we integrate to solve the diff. eq.?

Recall, in general, $\frac{dy}{dx} = f(x, y)$ is a first-order diff. eq.

Definition: Separable diff. eq.: If $f(x, y)$ in the equation $\frac{dy}{dx} = f(x, y)$ can be written as a function $g(x)$ (that depends solely on x) times a function $p(y)$ (that depends solely on y), then the diff. eq. is **separable**. In other words, $\frac{dy}{dx} = f(x, y)$ is separable if and only if

$$\frac{dy}{dx} = g(x) \cdot p(y).$$

Consider that we could rewrite this equation as $\frac{dy}{p(y)} = g(x) \cdot dx$. We could integrate this to get back to the solution function y . Here is our plan explicitly.

Method for Solving Separable Equations:

To solve the equation $\frac{dy}{dx} = g(x) \cdot p(y)$, rewrite it as $h(y) \cdot dy = g(x) \cdot dx$ where $h(y) = \frac{1}{p(y)}$.

Then integrate both sides $\int h(y) \cdot dy = \int g(x) \cdot dx$ to get $H(y) = G(x) + C$.

The last equation gives us an implicit solution to the original diff. eq..

Both constants of integration combined into one, $C \in \mathbb{R}$.

Additional Solutions: Constant functions $y \equiv c$ such that $p(c) = 0$ are also solutions to the diff. eq. but will *not* show up in this method. We will add them on to the solution.

Find the roots of the function $p(y)$.

The symbol \equiv means “defined to be equal”.

expl 1: Determine if these differential equations are separable. Identify the functions h and g .

a.) $\frac{ds}{dt} = t \cdot \ln(s^{2t}) + 8t^2$

Do you remember
your log rules?

$$\log_a(t^b) = b \cdot \log_a t$$

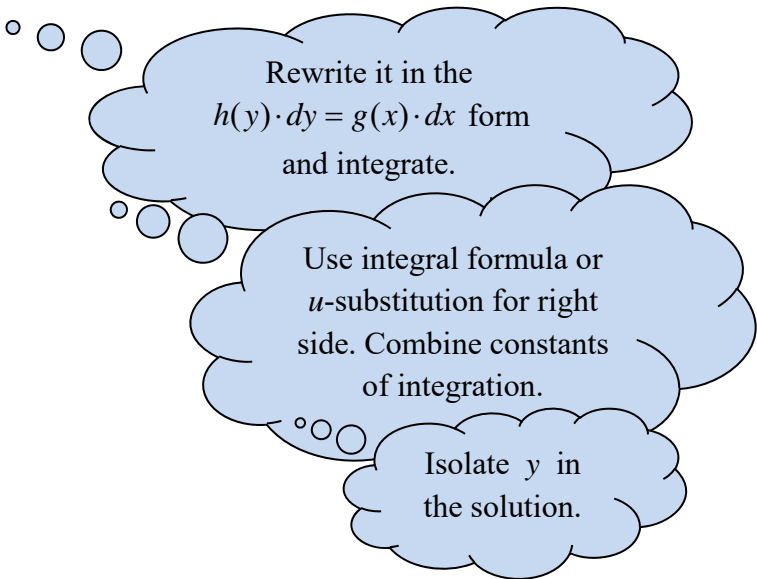

b.) $\frac{dy}{dx} - \sin(x + y) = 0$

How well do
you remember
trig. identities?

c.) $(xy^2 + 3y^2)dy - 2xdx = 0$

expl 2: Solve the equation.

$$\frac{dy}{dx} = \frac{x}{y^2 \sqrt{1+x}}$$

Rewrite it in the
 $h(y) \cdot dy = g(x) \cdot dx$ form
and integrate.

Use integral formula or
 u -substitution for right
side. Combine constants
of integration.

Isolate y in
the solution.

After all that, let's *not* forget those possible additional solutions in the form $y \equiv c$ such that $p(c) = 0$. So what is $p(y)$ and what values of c make it zero? Do we need to amend our solution?

expl 3: Solve the equation.

$$\frac{dx}{dt} - x^3 = x$$

Considering the switch
of variables, we look
for $h(x) \cdot dx = g(t) \cdot dt$.

Do you recall
partial fraction
decomposition?

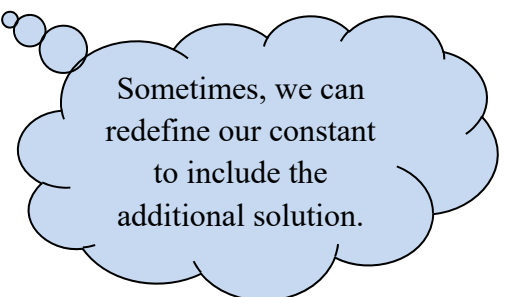

Be careful with
how you define
the constants.

Isolate x in the
solution. It might
take a bit of work.

(more room on next page)

(extra room)

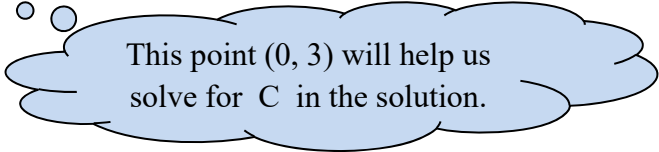

After all that, let's *not* forget those possible additional solutions in the form $x \equiv c$ such that $p(c) = 0$. So what is $p(x)$ and what values of c make it zero?

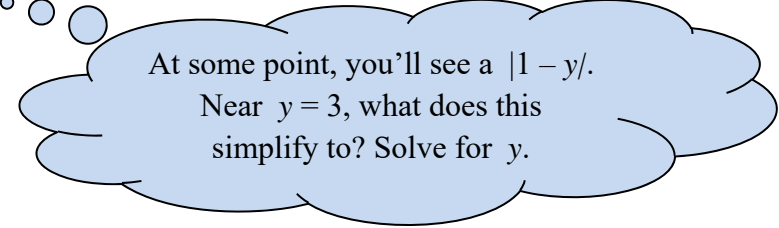

Sometimes, we can
redefine our constant
to include the
additional solution.

expl 4: Solve the initial value problem.

$$y' = x^3(1 - y), \quad y(0) = 3$$

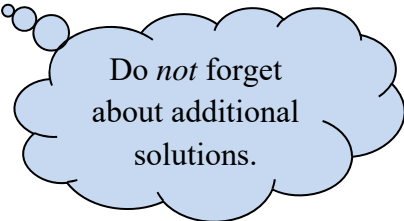

This point $(0, 3)$ will help us solve for C in the solution.

At some point, you'll see a $|1 - y|$.
Near $y = 3$, what does this simplify to? Solve for y .

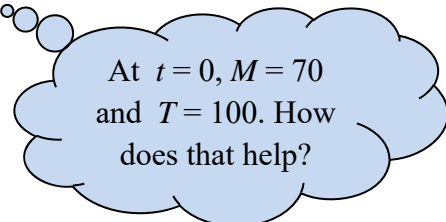

expl 5: **Newton's Law of Cooling:** If an object at temperature T is immersed in a medium having constant temperature M , then the rate of change of T is proportional to the difference of temperatures, $M - T$. This gives us the diff. eq. $\frac{dT}{dt} = k(M - T)$.

a.) Solve for T .

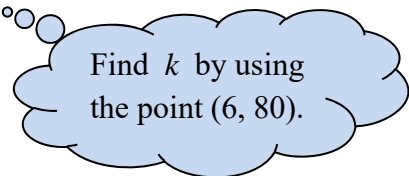

Do *not* forget
about additional
solutions.

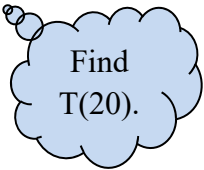

b.) A thermometer reading 100° Fahrenheit is placed in a medium having a constant temperature of 70° F. After 6 minutes, the thermometer reads 80° F. What is the reading after 20 minutes?

At $t = 0$, $M = 70$
and $T = 100$. How
does that help?

Find k by using
the point $(6, 80)$.

Find
 $T(20)$.
